## Vision Rehabilitation After Acquired Brain Injury

September 12, 2018

200 Mercy Circle  
Camp Pendleton  
CA 92055

Two thirds of all afferent nerves originate from the visual system. When there is brain injury such as blunt trauma or concussion, it is more common than not for there to be functional consequences to the

visual system: Visual processing, visual memory, eye-alignment, tracking ability, photophobia, poor visual spatial processing, visually induced balance disorders and more.

This seminar reviews many of the visual problems that follow brain injury, and the therapeutic opportunities that people have in order to recover more normal visual function and a better quality of life.
